Econometrics I

WRITTEN EXAMINATION

Wednesday April 25 2018, 10 am – 15 pm

Tools allowed: Pocket calculator

Passing rate. 50% of overall total, which is 100 points. For detailed grading

Criteria, see the course description.

The exam will be handed back: not decided

For the maximum number of points on each problem detailed and clear solutions are required.

If not indicated otherwise, the disturbance tem u_i in the models are assumed to fulfill the usual requirements of normality, homoscedasticity and independence.

Task 1 (24)

Assume the following model $Y_i=\beta X_i+u_i$

A) Derive the least square estimator of β. (8)

B) The result in task A should be $\hat{\beta} = \frac{\sum X_i Y_i}{\sum X_i^2}$. Show that the estimator is unbiased and find its variance. In your derivation specify where you use the assumption of uncorrelated errors and the assumption of constant error variance.(8)

C) Now assume that the error variance is proportional to the variable X. How should you transform the model to obtain constant error variance? Present the transformed model and show that the error variance in the transformed model is homoscedastic. (8)

Task 2 (8)

Which two of the following statements are not correct for the classical linear regression model: $Y_i=\beta_1+\beta_2X_{2i}+\beta_3X_{3i}+u_i$

a) $Cov(X_{2i},X_{3i})$ must be equal to zero

b) If $X_{2i}=2X_{3i}$ it is possible to estimate the individual parameters β_2 and β_3 using a simple linear regression model instead of the multiple model.

c) $E(u_i|X_{2i}) = E(u_i|X_{3i})$

d) $E(Y|X_{2i}+1,X_{3i}+1) - E(Y|X_2,X_3) = \beta_2+\beta_3$

e) If $X_{2i}=X_{3i}$ it is possible to estimate the sum of the individual parameters β_2 and β_3 using a simple linear regression model instead of the multiple model.

Task 3 (20)

The table below shows the number of death penalty verdicts (DPV) for cases involving multiple murders (TOTALS) in Florida between 1976 and 1987, classified by the race of the defendant and the race of the victim.

The following model will be studied: $ln\frac{P}{1-p} = \beta_1 + \beta_2 VR + \beta_3 DR$,

where P = probability that a multiple murder will get a death penalty, VR=1 if the victim is black, 0 if the victim is white and DR=1 if the defendant is black, DR = 0 if the defendant is white.

(See Jöreskog et al, Multivariate Analysis with LISREL, Springer Verlag, and references therein.)

A) Is the logistic regression significant? Specify the null- and alternative hypothesis and use relevant result in the estimation results to answer the question. (6)

B) For given victim calculate a 90% confidence interval for the ODDS of a death penalty if the defendant is black (e^{β_3}). (7)

C) Calculate the probability of getting a death penalty given VR=1 and DR=1 and compare it with the observed proportion for VR=1 and DR=1.(7)

Data Display

Row	DPV	VR	DR	TOTALS
1	53	0	0	467
2	11	0	1	48
3	0	1	0	16
4	4	1	1	143

Estimation results

Response Information

Variable	Value	Count
DPV	Event	68
	Non-event	606
TOTALS	Total	674

Logistic Regression Table

Predictor	Coef	SE Coef	Z	P	Odds Ratio
Constant	-2,05946	0,145846	-14,12	0,000	
VR	-2,40444	0,600600	-4,00	0,000	0,09
DR	0,867797	0,367074	2,36	0,018	2,38

Log-Likelihood = -209,478

Test that all slopes are zero: G = 21,886, DF = 2, P-Value = 0,000

Task 4 (23)

This exercise is based on the data in table 8.8 in Gujarati edition 5. In the table data for GDP, Employment and Fixed Capital for the years 1955 to 1974 in Mexico are presented. We shall use these observations to study the Cobb-Douglas production function:

$$lnGDP_t = \beta_1 + \beta_2 lnLabor_t + \beta_3 lnCapital_t + u_t.$$

We will assume that the assumptions are fulfilled for the classical linear regression model and disregard the problem with trending variables.

A) Interpret the parameter estimate of β_2.(5p)

B) Specify the null hypothesis and the alternative hypothesis that corresponds to the presented F-vlue=1719.20 and make a conclusion based on the result. (6).

C) Calculate a 90% confidence interval for $\beta_2 + \beta_3$ and interpret the result.(12p)

```

Task 5 (25)

Below and on the next page you find estimation results for the models:

Model 1: $Y_i = \beta_1 + \beta_2 X_{2i} + u_i$

Model 2: $Y_i = \beta_1 + \beta_2 X_{2i} + \beta_3 D_i + \beta_4 D_i X_{2i} + u_i$,

where D is a dummy variable that takes the value 0 for group one and the value 1 for group two. Below you find estimation results for Model 1 based on all observations and estimation results based on observations for group 1 only. The estimation results on the next page for Model 2 are based on all observations.

A) Use the results from Model 2 to write out the estimated equation for group one and group two separately. (5)

B) Perform a formal test of whether the beta-parameters are the same for the two groups. Be careful when you specify the hypothesis, test statistic, degrees of freedom, result and decision. (12)

C) Is the error variance the same for group 1 and group 2? Perform a formal test. (10)

Regression Analysis: Y versus X

The regression equation is
Y = - 3,01 + 0,0725 X

Predictor	Coef	SE Coef	T	P
Constant	-3,014	2,919	-1,03	0,313
X	0,07250	0,03941	1,84	0,079

S = 1,09889   R-Sq = 12,8%   R-Sq(adj) = 9,0%

Formula sheet, Econometrics I, Spring 2018

Under the simple linear model $Y_i = \beta_1 + \beta_2 X_i + u_i$, where $u_i \sim N(0, \sigma^2)$ and given independent pairs of observations $(Y_1, X_1), \ldots, (Y_n, X_n)$, the OLS estimators are:

$$
\begin{aligned}
\widehat{\beta}_1 &= \overline{Y} - \widehat{\beta}_2 \overline{X} \\
\widehat{\beta}_2 &= \frac{\sum (X_i - \overline{X})(Y_i - \overline{Y})}{\sum (X_i - \overline{X})^2} \\
\widehat{\sigma}^2 &= \frac{RSS}{n-2} = \frac{\sum \left(Y_i - \widehat{Y}_i\right)^2}{n-2}
\end{aligned}
$$

where $\widehat{Y}_i = \widehat{\beta}_1 + \widehat{\beta}_2 X_i$ and where $E(\widehat{\beta_1}) = \beta_1$, $E(\widehat{\beta_2}) = \beta_2$ and $E(\widehat{\sigma}^2) = \sigma^2$ and further

$$
\begin{aligned}
V(\widehat{\beta}_1) &= \frac{\sum X_i^2}{n \sum (X_i - \overline{X})^2} \sigma^2 \\
V(\widehat{\beta}_2) &= \frac{\sigma^2}{\sum (X_i - \overline{X})^2} \\
V(\widehat{Y}_0) &= \sigma^2 \left(\frac{1}{n} + \frac{(X_0 - \overline{X})^2}{\sum (X_i - \overline{X})^2} \right) \\
V(Y_0 - \widehat{Y}_0) &= \sigma^2 \left(1 + \frac{1}{n} + \frac{(X_0 - \overline{X})^2}{\sum (X_i - \overline{X})^2} \right)
\end{aligned}
$$

Distributional results:

$$
\begin{aligned}
\frac{\widehat{\beta}_i - \beta_i}{se(\widehat{\beta}_i)} &\sim t(n-2), \quad i = 1, 2 \\
\frac{\widehat{\sigma}^2 (n-2)}{\sigma^2} &\sim \chi^2(n-2)
\end{aligned}
$$

Coefficient of determination:

$$
r^2 = \frac{ESS}{TSS} = 1 - \frac{RSS}{TSS} = 1 - \frac{\sum \left(Y_i - \widehat{Y}_i\right)^2}{\sum (Y_i - \overline{Y})^2}
$$

Coefficient of correlation:

$$
r = \frac{\sum (X_i - \overline{X})(Y_i - \overline{Y})}{\sqrt{\sum (X_i - \overline{X})^2 \sum (Y_i - \overline{Y})^2}}
$$

where $r = \pm\sqrt{r^2}$

If we let $Y_i^* = w_1 Y_i$ and $X_i^* = w_2 X_2$, then

$$\widehat{\beta}_1^* = w_1 \widehat{\beta}_1, \quad \widehat{\beta}_2^* = \left(\frac{w_1}{w_2}\right) \widehat{\beta}_2, \quad \widehat{\sigma}^{*2} = w_1^2 \widehat{\sigma}^2$$

Under the multiple linear regression model $Y_i = \beta_1 + \beta_2 X_{2i} + \cdots + \beta_k X_{ki} + u_i$, where $u_i \sim N(0, \sigma^2)$ and given independent vectors of observations $(Y_1, X_{21}, \ldots, X_{k1}), \ldots, (Y_n, X_{2n}, \ldots, X_{kn})$, the following holds for the OLS estimators:

$$\widehat{\sigma}^2 = \frac{RSS}{n-k} = \frac{\sum \left(Y_i - \widehat{Y}_i\right)^2}{n-k}$$

$$\frac{\widehat{\beta}_i - \beta_i}{se(\widehat{\beta}_i)} \sim t(n-k), \quad i = 1, \ldots, k$$

$$\frac{\widehat{\sigma}^2 (n-k)}{\sigma^2} \sim \chi^2(n-k)$$

The multiple coefficient of determination:

$$R^2 = \frac{ESS}{TSS} = 1 - \frac{RSS}{TSS} = 1 - \frac{\sum \left(Y_i - \widehat{Y}_i\right)^2}{\sum \left(Y_i - \overline{Y}\right)^2}$$

Adjusted:

$$\overline{R}^2 = 1 - \frac{RSS/(n-k)}{TSS/(n-1)}$$

Testing $H_0 : \beta_2 = \ldots \beta_k = 0$:

$$F = \frac{ESS/(k-1)}{RSS/(n-k)} = \frac{\sum \left(\widehat{Y}_i - \overline{Y}\right)^2 /(k-1)}{\sum \left(Y_i - \widehat{Y}_i\right)^2 /(n-k)}$$

Comparing an "old" model with a "new" (larger):

$$F = \frac{(ESS_{new} - ESS_{old})/\text{number of new regressors}}{RSS_{new}/(n - \text{number of parameters in the new model})}$$
$$= \frac{(R^2_{new} - R^2_{old})/\text{number of new regressors}}{(1 - R^2_{new})/(n - \text{number of parameters in the new model})}$$

Comparing an "unrestricted" model with a "restricted":

$$F = \frac{(RSS_R - RSS_{UR})/m}{RSS_{UR}/(n-k)} = \frac{(R^2_{UR} - R^2_R)/m}{(1 - R^2_{UR})/(n-k)}$$

where m is the number of linear constraints and k is the number of parameters in the unrestricted model.

Variance inflation factor:

$$VIF_j = \frac{1}{1 - R_j^2}$$

Auxiliary regression:

$$F_j = \frac{R_j^2/(k-2)}{(1 - R_j^2)/(n-k+1)}$$

where $R_j^2 = R^2$ in the regression of x_j on the remaining $(k-2)$ regressors.

Tests of heteroscedasticity: (all test statistics are evaluated under the null hypothesis of no heteroscedasticity)

White's test: Regress $\hat{u}_i^2$ against the $k-1$ regressors and the squares of these. Test statistic: $n\,R^2 \overset{appr}{\sim} \chi^2(2(k-1))$

Glejser test: Regress $|\hat{u}_i|$ against the regressor X_j (one regressor at a time) Test statistic: t-test of the slope

Park test: Regress $ln\hat{u}_i^2$ against the regressor lnX_j, (one regressor at a time) Test statistic: t-test of the slope

Goldefeld Quandt test of equal variances in two separate regressions: Test statistic: $\frac{S_1^2}{S_2^2} \sim F(n_1 - k_1, n_2 - k_2)$

Tests of autocorrelation:

The Runs test: For R = number of runs, where $N = N_1 + N_2$ total number of observations:

$$E(R) = \frac{2N_1N_2}{N} + 1$$

$$V(R) = \frac{2N_1N_2(2N_1N_2 - N)}{N^2(N-1)}$$

The Durbin Watson d statistic:

$$d = \frac{\sum_{t=2}^{n} (\widehat{u}_t - \widehat{u}_{t-1})^2}{\sum_{t=1}^{n} \widehat{u}_t^2}$$

Breusch Godfrey test: Nullypothesis: H_0: $\rho_1 = \rho_2 = \ldots = \rho_K = 0$
Test statistic: nR^2 from the regression of $\hat{u}_t$ on the regressors which have produced $\hat{u}_t$ plus lagged $\hat{u}_t$ up to lag K.
n = the number of observations used in this regression.
The test statistic is approximately $\chi^2(K)$

Akaike's information criterion:

$$AIC = \frac{e^{2k/n} RSS}{n}$$

Schwartz's information citerion:

$$SIC = \frac{n^{k/n} RSS}{n}$$

Mallow's C_p criterion:

$$C_p = \frac{RSS_p}{\hat{\sigma}^2} - (n - 2p)$$

Logistic regression (logit model):

$$P(Y = 1) = \frac{1}{1 + e^{-(\beta_1 + \beta_2 X_2 + \cdots + \beta_k X_k)}}, \quad ln(\frac{P(Y = 1)}{1 - P(Y = 1)}) = \beta_1 + \beta_2 X_2 + \cdots + \beta_k X_k$$

TABLE D.1
Areas Under the Standardized Normal Distribution

Example

$\Pr(0 \le Z \le 1.96) = 0.4750$

$\Pr(Z \ge 1.96) = 0.5 - 0.4750 = 0.025$

2.8	.4974	.4975	.4976	.4977	.4977	.4978	.4979	.4979	.4980	.4981
2.9	.4981	.4982	.4982	.4983	.4984	.4984	.4985	.4985	.4986	.4986
3.0	.4987	.4987	.4987	.4988	.4988	.4989	.4989	.4989	.4990	.4990

Note: This table gives the area in the right-hand tail of the distribution (i.e., $Z \ge 0$). But since the normal distribution is symmetrical about $Z = 0$, the area in the left-hand tail is the same as the area in the corresponding right-hand tail. For example, $\Pr(-1.96 \le Z \le 0) = 0.4750$. Therefore, $\Pr(-1.96 \le Z \le 1.96) = 2(0.4750) = 0.95$.

TABLE D.2
Percentage Points of the t Distribution

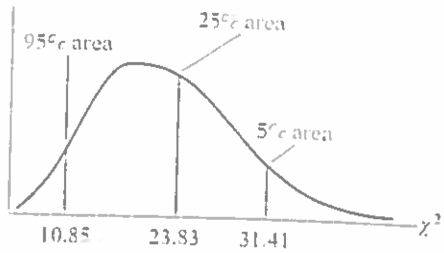
∞	0.674	1.282	1.645	1.960	2.326	2.576	3.090

Note: The smaller probability shown at the head of each column is the area in one tail; the larger probability is the area in both tails.

TABLE D.4
Upper Percentage Points of the χ^2 Distribution

Example

$\Pr(\chi^2 > 10.85) = 0.95$
$\Pr(\chi^2 > 23.83) = 0.25$ for df = 20
$\Pr(\chi^2 > 31.41) = 0.05$



Degrees of freedom \ Pr	.995	.990	.975	.950	.900

TABLE D.3 Upper Percentage Points of the F Distribution

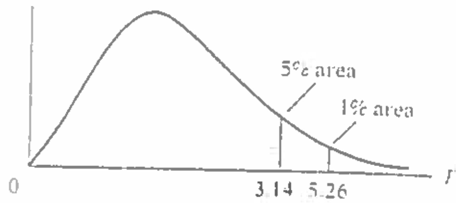
Example

$Pr(F > 1.59) = 0.25$

$Pr(F > 2.42) = 0.10$ for df $N_1 = 10$

$Pr(F > 3.14) = 0.05$ and $N_2 = 9$

$Pr(F > 5.26) = 0.01$



df for denominator N_2	Pr	df for numerator N_1: 1	2	3	4	5	6	7	8	9	10	11	12

Note: n = number of observations, k' = number of explanatory variables excluding the constant term.

Source: This table is an extension of the original Durbin–Watson table and is reproduced from N. E. Savin and K. J. White, "The Durbin–Watson Test for Serial Correlation with Extreme Small Samples or Many Regressors," *Econometrica*, vol. 45, November 1977, pp. 1989–96 and as corrected by R. W. Farebrother, *Econometrica*, vol. 48, September 1980, p. 1554. Reprinted by permission of the Econometric Society.

EXAMPLE 1 If $n = 40$ and $k' = 4$, $d_L = 1.285$ and $d_U = 1.721$. If a computed d value is less than 1.285, there is evidence of positive first-order serial correlation; if it is greater than 1.721, there is no evidence of positive first-order serial correlation; but if d lies between the lower and the upper limit, there is inconclusive evidence regarding the presence or absence of positive first-order serial correlation.

Durbin–Watson d Statistic: Significance Points of d_L and d_U at 0.01 Level of Significance

	k′ = 1		k′ = 2		k′ = 3		k′ = 4		k′ = 5		k′ = 6		k′ = 7		k′ = 8		k′ = 9		k′ = 10

SU, DEPARTMENT OF STATISTICS

Room: UG **Anonymous code:** 0025-AGK **Sheet number:** 1

Task 1.

A) Model: $Y_i = \beta x_i + u_i$

$$SSE = \Sigma (Y_i - \hat{Y}_i)^2 = \Sigma (Y_i - \hat{\beta} \cdot x_i)^2$$

$$\frac{dSSE}{d\beta} = \Sigma -2x_i(Y_i - \hat{\beta} x_i) = 0$$

$$\Rightarrow \Sigma X_i Y_i - \hat{\beta} \cdot \Sigma X_i^2 = 0$$

$$\Rightarrow \hat{\beta} = \frac{\Sigma X_i Y_i}{\Sigma X_i^2}$$

8

R

B) $$E(\hat{\beta}) = E\left[\frac{\Sigma X_i Y_i}{\Sigma X_i^2}\right] = \frac{1}{\Sigma X_i^2} E[\Sigma X_i Y_i]$$

$$= \frac{\Sigma X_i \cdot E(Y_i)}{\Sigma X_i^2} = \frac{\Sigma X_i \cdot \beta X_i}{\Sigma X_i^2}$$

$$= \frac{\beta \cdot \Sigma X_i^2}{\Sigma X_i^2} = \beta.$$

R

Thus, $\hat{\beta}$ is an unbiased estimator for β.

$$V(\hat{\beta}) = V\left[\frac{\Sigma X_i Y_i}{\Sigma X_i^2}\right] = \frac{1}{(\Sigma X_i^2)^2} V[\Sigma X_i Y_i]$$

$$V(\Sigma X_i Y_i) = \Sigma V(X_i Y_i) + 2\Sigma\Sigma_{i \neq j} \text{cov}(X_i Y_i, X_j Y_j)$$

8

Since we assume that error terms are uncorrelated

$$\text{cov}(X_i Y_i, X_j Y_j) = X_i X_j \text{cov}(Y_i, Y_j) = X_i X_j \text{cov}(u_i, u_j) = 0$$

Then we get $V(\Sigma X_i Y_i) = \Sigma V(X_i Y_i)$

In addition, we assume the error terms are homoscedastic.

$$V(\Sigma X_i Y_i) = \Sigma V(X_i Y_i) = \Sigma X_i^2 \cdot V(Y_i) = \Sigma X_i^2 \sigma^2 = \sigma^2 \Sigma X_i^2$$

Thus we get $$V(\hat{\beta}) = \frac{\sigma^2 \Sigma X_i^2}{(\Sigma X_i^2)^2} = \frac{\sigma^2}{\Sigma X_i^2}$$

R

c). From the assumption.

$$V(u_i) = \sigma_i^2 = \sigma^2 \cdot X_i .$$

Inorder for the error term to be constant, we devide the both side of our model with $\sqrt{X_i}$

$$\frac{Y_i}{\sqrt{X_i}} = \beta \frac{X_i}{\sqrt{X_i}} + \frac{u_i}{\sqrt{X_i}}$$

$$\frac{Y_i}{\sqrt{X_i}} = \beta \cdot \sqrt{X_i} + \frac{u_i}{\sqrt{X_i}}$$

$$V\left(\frac{u_i}{\sqrt{X_i}}\right) = \frac{V(u_i)}{X_i} = \frac{\sigma^2 \cdot X_i}{X_i} = \sigma^2$$

Thus, the transformed model has homoscedastic error term.

8

Task 2.

a) and c) ~~A~~

8

SU, DEPARTMENT OF STATISTICS

Room: UG Anonymous code: 0025-AGK Sheet number: 2

Task 3

A) $H_0: \beta_2 = \beta_3 = 0$

$H_a: \beta_2 \neq 0$ or $\beta_3 \neq 0$ or both

6

Test statistic: $G = 21.886$

Since p-value = 0.000, we reject H_0 and conclude that this logistic regression model is significant.

ok

B) Since $E(e^{\hat{\beta}_3}) = e^{\beta_3}$

the confidence interval for e^{β_3} is $e^{\hat{\beta}_3} \pm t_{\alpha/2} \cdot S_{(e^{\hat{\beta}_3})}$

$e^{\hat{\beta}_3} = e^{0.867797}$, $t_{.05}^{671} \approx z_{.05} = 1.645$. $S_{(e^{\hat{\beta}_3})} = e^{0.367074}$

90% CI: $e^{0.867797} \pm 1.645 \cdot e^{0.367074}$

$\Rightarrow 2.382 \pm 2.375$

$\Rightarrow (0.007, 4.757)$

-4 3

C) $E(\hat{p} \mid VR=1, PR=1) = \dfrac{1}{1+e^{-(-2.05946-2.40444+0.867797)}}$

$= \dfrac{1}{1+e^{3.596103}} \approx 0.02670$

7

The observed proportion: $\frac{4}{143} \approx 0.02797$

The expected value of $\hat{p}$ from this model is very close to the observed proportion, which means that this model well explaines the probability that a multiple murder will get a death penalty.

16

Task 4

$$\ln GDP_t = \beta_1 + \beta_2 \ln Labor_t + \beta_3 \ln Capital_t + u_t$$

A) One percentage increase in Labor is associated with β_2 percentage ~~increase~~ change in GDP given that other variables are constant. on average

3

B)

$$H_0 : \beta_2 = \beta_3 = 0$$

$$H_a : \beta_2 \neq 0 \text{ or } \beta_3 \neq 0$$ both

5

Since corresponding p-value = 0.0000, we reject H_0 and conclude that this regression model is significant. which means ?

C) Since $E(\hat{\beta}_2 + \hat{\beta}_3) = E(\hat{\beta}_2) + E(\hat{\beta}_3) = \beta_2 + \beta_3$.

the confidence interval for $\beta_2 + \beta_3$ is expressed by

$$\hat{\beta}_2 + \hat{\beta}_3 \pm t_{.05}^{(17df)} S_{(\hat{\beta}_2 + \hat{\beta}_3)}$$

$$V(\hat{\beta}_2 + \hat{\beta}_3) = V(\hat{\beta}_2) + V(\hat{\beta}_3) + 2\,cov(\hat{\beta}_2, \hat{\beta}_3)$$

$$= (.03448182) + (.00891459) + 2(-.01703459)$$

$$= .00912759$$

90% CI for $\beta_2 + \beta_3$: $(.3397362) + (.8459951) \pm 1.740 \sqrt{.00912759}$

$\Rightarrow$ 1.1857 ± 0.1662

$\Rightarrow$ $(1.0195 \ ; \ 1.3519)$

12

With 90% confidence, we conclude that GDP is increasing return to scale, because the CI for $\beta_2 + \beta_3$ is greater than 1. ?

20

SU, DEPARTMENT OF STATISTICS

Room: UG Anonymous code: 0625-AGK Sheet number: 3

Task 5

Model 1: $Y_i = \beta_1 + \beta_2 X_{2i} + u_i$

Model 2: $Y_i = \beta_1 + \beta_2 X_{2i} + \beta_3 D_i + \beta_4 D_i X_{2i} + u_i$

A)

$$\begin{cases} \hat{Y}_{1i} = \hat{\beta}_1 + \hat{\beta}_2 X_{2i} \\ \hat{Y}_{2i} = \hat{\beta}_1 + \hat{\beta}_2 X_{2i} + \hat{\beta}_3 + \hat{\beta}_4 X_{2i} = (\hat{\beta}_1 + \hat{\beta}_3) + (\hat{\beta}_2 + \hat{\beta}_4) X_{2i} \end{cases}$$

$$\Rightarrow \begin{cases} \hat{Y}_{1i} = -5.342 + 0.11151 X_{2i} \\ \hat{Y}_{2i} = -3.353 + 0.06649 X_{2i} \end{cases}$$

5

4 ok

B)

$H_0: \beta_3 = \beta_4 = 0$

$H_a: \beta_3 \neq 0$ or $\beta_4 \neq 0$

Test Statistic: $F = \frac{RSS_R - RSS_{UR} / m}{RSS_{UR} / n-k} \sim F(m, n-k)$

given H_0 is true and $u_i \sim IN(0, \sigma^2)$

Decision rule: we reject H_0 if $F_{obs} > F_{(2,21)}$

Result: $F_{obs} = \frac{(27.774 - 16.7871)/2}{16.7871/21} \approx 6.8721$

10

$F^{.05}_{(2,22)} < F^{.05}_{(2,21)} < F^{.05}_{(2,20)} \Rightarrow 3.44 < F^{.05}_{(2,21)} < 3.49$

Since $F_{obs} > F^{.05}_{(2,21)}$ we reject H_0 with 5% significance level

and conclude that the beta-parameters are not the same for the two groups.

(c) $H_0: \sigma_1^2 = \sigma_2^2$

$H_a: \sigma_1^2 \neq \sigma_2^2$ (Significance level = 5%)

Let. RSS_{UR} : The residual sum of squares for the unrestricted model

RSS_1 : The residual sum of squares for group 1

RSS_2 : The residual sum of squares for group 2

$RSS_{UR} = RSS_1 + RSS_2$

$\Rightarrow RSS_2 = RSS_{UR} - RSS_1 = 16.7871 - 7.7294 = 9.0577$

Test statistic : $F = \dfrac{S_2^2/\sigma_2^2}{S_1^2/\sigma_1^2} \sim F(n_2-k, n_1-k)$

where n_1 and n_2 are the number of observations for group 1 and 2.

k denotes the number of regressors, given that Ho is true

Decision rule : We reject Ho if $F_{obs} > F_{(10-2, 15-2)}$

Result : $F_{obs} = \dfrac{RSS_2/n_2-k}{RSS_1/n_1-k} = \dfrac{9.0577/8}{7.7294/13} \approx 1.9043$

$F^{.05}_{(8,13)} = 2.77$

Since $F_{obs} < F^{.05}_{(8,13)}$, we do not have enough evidence to reject Ho. The error variance is the same for the two groups.

10

25
